Appetite for LNG grows, but industry still struggling

By Peter Caro, Director, Area Sales, Aspen Technology Australia

Appetite for LNG grows, industry struggles
Despite record low LNG prices and increasing capital costs for new production plants, there is pressure on the industry in Asia-Pacific to increase capacity by improving efficiencies and constructing more facilities. Demand for LNG as a carbon-friendly energy source continues to grow in many regions, with appetite highest within Asia-Pacific. Before the decade’s end, when most of the current under-construction projects reach production, there will be a short-lived period of oversupply. But by 2021 the world will need additional supply capacity – more output, more plants.

Nonetheless, in the current volatile economic climate, and because of the project construction timelines of five to ten years, investors are reluctant to commit to new LNG projects.

At a macro level, there are engineering design solutions that can aid in mitigating investment risk, assist with optimising design and lowering construction costs, as well as, at a detailed level, improve efficiencies for existing facilities.

LNG price on the slide
The crude oil spot price continues to fall, and since the LNG price is indexed to the oil price, LNG supply prices are racing to the bottom. This is despite the fact that in the Asia-Pacific region LNG supply contracts are long-term (as Australia has signed with Japan), so these contracts really only delay the inevitable. From the start of 2014, the LNG price at the Japan/Korea Marker (JKM) has fallen 60 per cent.

The impact on existing large Australian LNG plants, mostly using offshore gas feeds, is devastating, and they are scrambling to find ways to improve efficiency and reduce operating costs (OPEX).

Optimising the existing plant, with a focus on the liquefaction process (40 per cent of the operating costs) offers the quickest and most significant OPEX reduction. Optimising this process by implementing advanced process control (APC) can improve efficiency and bolster plant reliability, resulting in greater yield and lower costs.

LNG demand on the climb
The demand for LNG from the Asia-Pacific regions continues to grow at around 4 per cent pa. This is despite the fact that, since 2012, Japanese consumption has dropped as they recommission their nuclear power plants that were mothballed after Fukushima. The excess supply has been absorbed by increased purchasing from China and Korea, but in anticipation of significantly higher demand, offshore natural gas and CSG-to-LNG projects were launched nearly a decade ago, and as these come online there will be an over-supply for a few years, and then a supply shortage from 2021. It is anticipated that by 2017 Australia will be the world’s largest LNG exporter.

According to Philip Olivier(1),
Modelling the market

To further reduce FID hesitation in this volatile LNG market, investors demand greater assurance than ever before that every business scenario has been simulated and tested.

Economic scenarios such as future oil prices, demand, the impact of renewable energy, long-term contract viability, political stability, and much more, need to be modelled by the economic strategists.

As importantly, it is imperative that the potential LNG project – including conceptual design, detailed design, project costing, anticipated throughput, planned efficiency, operations and maintenance, as well as ROI – is extensively modelled and tested to take into account every conceivable scenario. This includes: gas feed composition variations, gas feed pressure changes, output demand volatility, environmental considerations such as ambient temperature (after all, LNG is a cryogenic process), and plant reliability impacting shutdowns and start-ups.

The latest process plant design software tools incorporate the option to perform realistic and extensive technical simulations.

Chiyoda Corporation, the largest Japanese integrated engineering company and the world’s leading LNG contractor with major involvement in the Inpex Ichthys project off Darwin, uses these tools to verify operability and controllability of new LNG plants. Chiyoda examines possible transient scenarios, such as operation procedures for start-up and shut-down, including compressors. This allows Chiyoda to design more reliable plants.

Down with downtime

The extremely ‘tight’ LNG industry demands high plant reliability and minimal downtime. This requirement is even more critical in CSG-to-LNG plants due to the upstream implications of a gas train malfunction.

Typically an LNG train is supplied by hundreds of CSG wells. Less groundwater needs to be pumped out and treated the longer a well is in operation. Consequently, if the gas demand on wells is reduced due to a train shut, then the groundwater builds up and has to be pumped out in greater volume at a later stage, costing more. Alternatively, the wells can be allowed to supply gas as normal but the gas is then flared to the atmosphere: both costly and environmentally harmful. The train is also not producing and earning revenue.

A prerequisite for success in this market is robust detailed overall design, coupled with intensive design and simulation testing of each phase of the process, each sub-process, and even individual critical pieces of equipment. Implementing a software engineering tool incorporating the ability to drill down to component level can ensure sufficient detailed simulation and testing, delivering a robust, reliable LNG facility.

Within Fives for example, the Cryogenic|Energy business group is a major manufacturer of brazed aluminium heat exchangers (BAHX), using exchanger design and rating simulation software products to understand the exchanger’s impact on the entire process rather than as a sole unit. Specifically, Fives wanted to monitor multiple BAHX in series, and the real pressure levels at BAHX outlets along with thermo-hydraulic coupling to optimise the final design of the cold box. This strategy allowed Fives to optimise the equipment design in the context of the process, but also to optimise CAPEX and OPEX simultaneously over the life of the equipment.

Big data, big gas

One of the strongest challenges in oil and gas is managing information to implement efficiency strategies. According to Curtin University’s Dr Brian Evans(2), Director of Subsea Engineering Projects, “Our ability to become lean and mean will come down to our ability to master data analytics.”

The second report in Lloyd’s Register Energy’s Oil and Gas Technology Radar series maintains that any number of reasons can be cited for companies’ inability to use data more effectively. Simply handling and safely storing the large volumes of data being collected is a challenge. The same is true of dealing with unstructured data e.g. data originating, for example, from images or maps, or text embedded in email.

According to Duco de Haan(3), Commercial Development Director at Lloyd’s Register Energy, “Two factors stand out as hindrances to upstream companies’ better use of data. Silos (in companies) are the biggest problem. The lack of data integration across different parts of the business is rated the toughest challenge oil and gas firms face in improving their use of data.

Silos (in companies) are the biggest problem. The lack of data integration across different parts of the business is rated the toughest challenge oil and gas firms face in improving their use of data.

The current low oil/LNG prices will not continue for much longer, especially when demand outstrips supply, and then returns on investment will be meaningful.

But it is essential that owners of existing and planned LNG facilities employ the latest engineering software tools to ensure reliable and ‘proven by simulation’ design, efficient processes, and optimised process control. In this way risks can be minimised and ROI maximised.
